1

Motivation: Compositionality

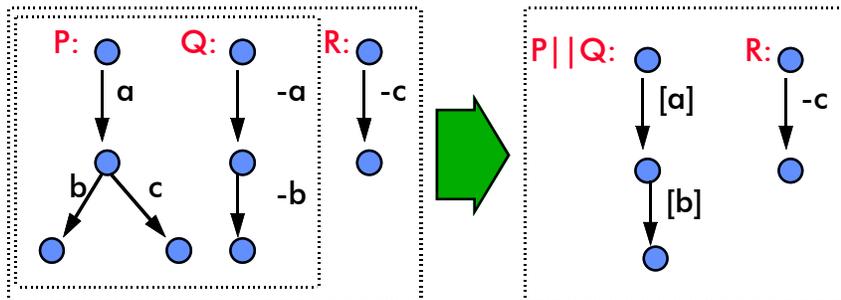

- ◆ Compositionality \cong Modularity
 - ◆ Ability to “compose” verifications of modules to verify a larger system
 - ◆ Logic example: Verify a program using pre- and post-conditions of verified procedures
 - ◆ Practical requirement: Verification or analysis results must be summarizations
- ◆ Compositionality in finite-state verification
 - ◆ Hierarchical analysis, summarizing results at each level
 - ◆ Potentially control state-space explosion

CIS 610, W98

2/16/98

2

Non-Compositional Analysis

- ◆ We cannot find all behaviors of $P||Q||R$ by finding behaviors of $P||Q$, then composing with R

CIS 610, W98

2/16/98

3

Adding Compositionality ...

- ◆ We want algebraic structure
 - ◆ Commutativity, associativity, and a congruence
 - ▲ e.g., $A+B = C \Rightarrow A+D+B = A+B+D = (A+B)+D = C+D$
- ◆ Needed:
 - ◆ Account for “potential” behaviors of a subsystem
 - ▲ in $(P||Q)||R$, the partial result $P||Q$ should include action b
 - ◆ ... but limit to interface actions
 - ▲ record “potential” behaviors only if they are visible outside a module (e.g., actions a and b don't matter to process R)
 - ◆ ... and simplify subsystem analyses
 - ▲ the difference between $[a]$ and $[b]$ should not matter outside the subsystem $P||Q$

CIS 610, W98

4

Processes as Terms

- ◆ Description of cooperating processes
 - ◆ Terms: similar to regular expressions
 - ▲ Context free processes are describable but too hairy
 - ◆ Process graphs: state machines denoted by terms
 - ▲ Regular processes denote finite-state process graphs
- ◆ Algebraic laws
 - ◆ Associative, commutative laws and substitution of equals for equals (and “less for equals”) for incremental reasoning:
 - $X = A||B$ implies $X||C = A||B||C$ (equivalence)
 - $X \leq A||B$ implies $X||C \leq A||B||C$ (preorder)

CIS 610, W98

2/16/98

5

Process Expressions

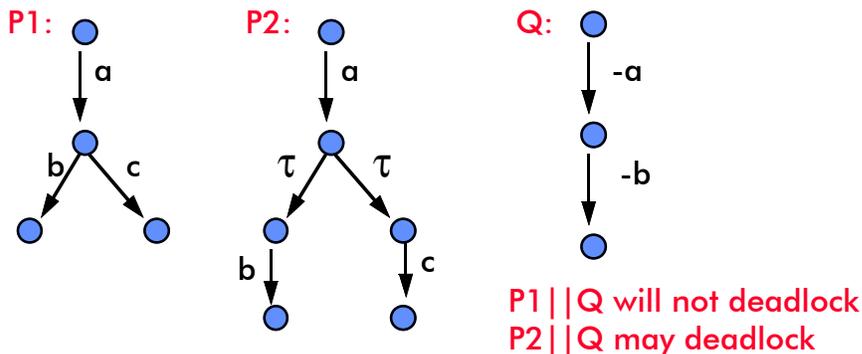

- ◆ Constants
 - δ (deadlock, or no action)
 - τ (internal, unobservable action, similar to ϵ)
 - a, b, c, \dots Observable actions
- ◆ Expressions formed from
 - $;$ (sequence, with $a;b$ abbreviated as ab)
 - $+$ (choice)
 - $|$ (synchronization of 2 events)
 - $aP||bQ = (a|b)(P||Q) + a(P||bQ) + b(aP||Q)$

CIS 610, W98

2/16/98

6

Why $\tau \neq \epsilon$

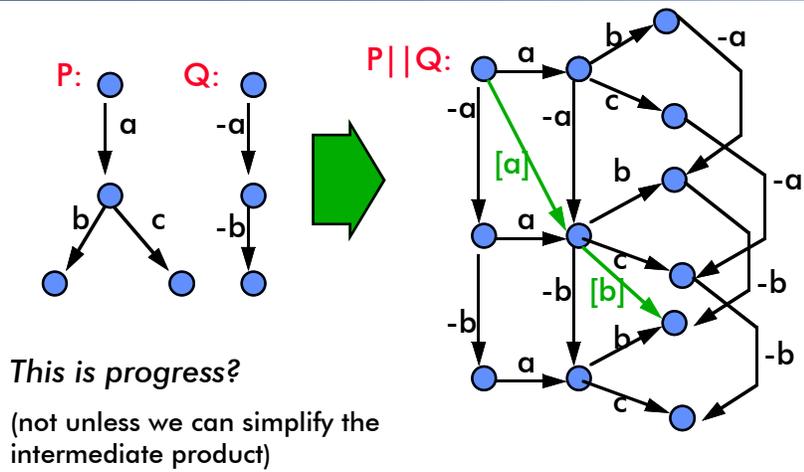

The other axioms of regular expressions come across without change, but note $ab+ac = a(\tau b + \tau c)$.

Synchronization

- ◆ $aP || bQ = (a|b)(P || Q) + a(P || bQ) + b(aP || Q)$
i.e., one moves first or else they move together
- ◆ In general, $a|b$ is some action c
- ◆ In CCS, $a|-a$ is τ , other pairs are δ
 - ◆ synchronization is rendezvous between action and co-action, and rendezvous is unobservable by other processes
- ◆ In CSP, $a|a$ is a , other pairs are δ
 - ◆ synchronization is agreement to do the same thing

Product of Processes

CIS 610, W98

2/16/98

9

Equivalence and Congruence

- ◆ Language equivalence is too coarse:
 - ◆ $ab + ac = a(b+c)$, which we have seen is wrong
 - ◆ We want something nearly as coarse, but preserving deadlock, cheap to check and compute quotients
- ◆ Bisimulation:
 - ◆ $P=Q$ iff $P \xrightarrow{-a} P'$ implies $Q \xrightarrow{-a} Q'$ and $P'=Q'$
 $Q \xrightarrow{-a} Q'$ implies $P \xrightarrow{-a} P'$ and $P'=Q'$
 - ◆ Strong bisim equivalent if we consider t an action
 - ◆ Weak bisim equivalent if an action is $a\tau^*$
 - ◆ Cheap to compute: similar to DFA minimization

CIS 610, W98

2/16/98

10

Abstraction and Restriction

- ◆ Abstraction: Substitute τ for a
 - ◆ Meaning: I don't care about a in this context
 - ◆ Especially: I don't interact with that action
- ◆ Restriction: Substitute δ for a
 - ◆ Meaning: That can't happen in this context
 - ◆ Especially: That interface isn't visible here
- ◆ At module boundaries,
 - ◆ Abstract actions that can happen "in the box"
 - ◆ Restrict actions in internal interfaces

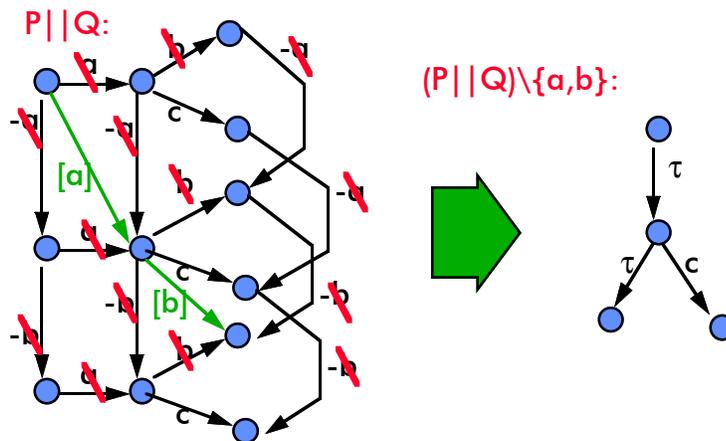

CIS 610, W98

2/16/98

11

Simplifying $P || Q$

- ◆ Restrict a, b and abstract $[a], [b]$

CIS 610, W98

2/16/98

12

Preorder and Precongruence

- ◆ We don't always want equivalence
 - ◆ We want to permit looser specs, like a super/sub-type relation among processes
 - ◆ Example: Bounded queue of unspecified length
 - ◆ A "preorder" relates specification \leq implementation
- ◆ The "testing" preorders
 - ◆ may: language inclusion
 - ▲ if p may pass a test, q may pass that test
 - ◆ must: failures inclusion
 - ▲ if p must pass a test, q must pass that test

CIS 610, W98

2/16/98

13

Why should I care?

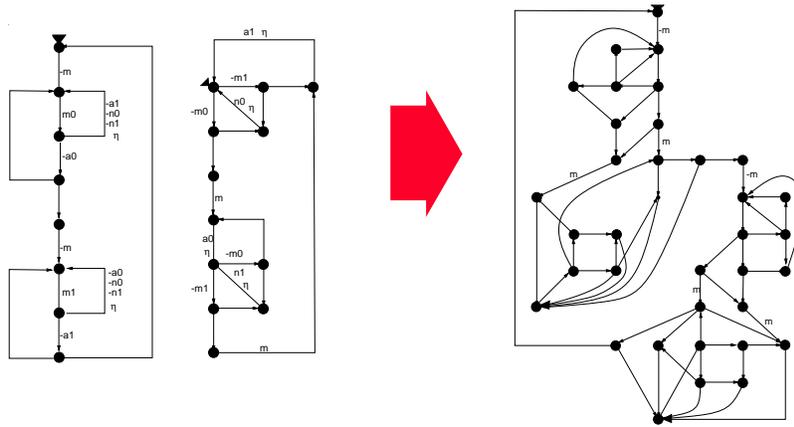

- ◆ Congruence (or preferably pre-congruence) is a useful definition of conformance of an implementation to an interface specification
- ◆ Process product permits one to say "these processes together meet that spec"
- ◆ Abstraction and restriction are the semantic building blocks for modularity
- ◆ Algebraic structure is essential (but not sufficient) for reasoning hierarchically about complex systems

14

State-space exploration example: Alternating Bit Protocol

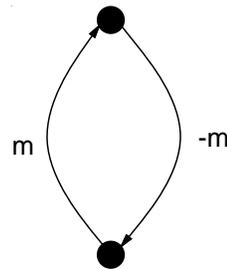

CIS 610, W98

2/16/98

15

Alternating Bit Protocol: After reduction

- ◆ After restriction and abstraction, process graphs can be reduced to equivalent form with respect to a congruence relation

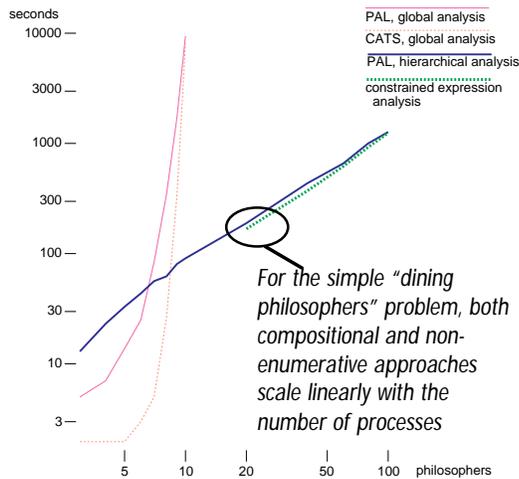

... but radical reductions in process graph size occur only when the system to be analyzed is "well-structured"

CIS 610, W98

2/16/98

16

Scalable analysis

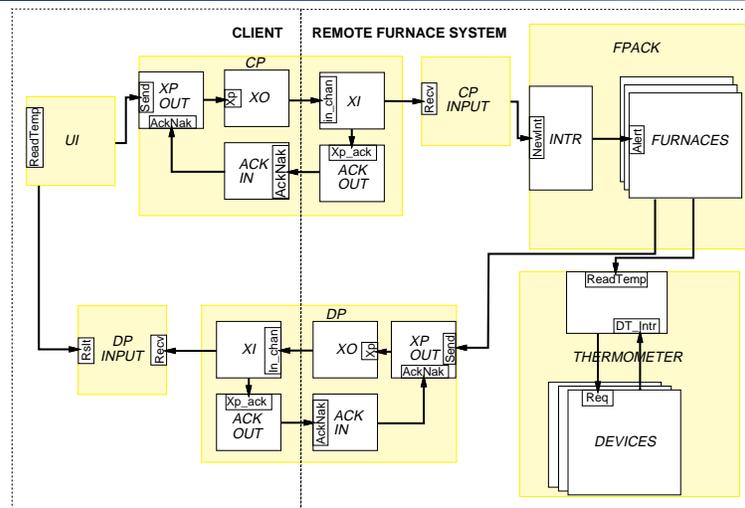

- ◆ When compositional analysis "works", reductions at intermediate steps keep state-space to manageable proportions
- ◆ The question is, when does (or can) it work?

CIS 610, W98

2/16/98

17

An example (redesigned)

2/16/98

18

Compositional analysis of revised design

CIS 610, W98

2/16/98

19

Experience with Compositional Analysis using Process Algebra

- ◆ Has worked well for well-structured designs, poorly for code and “as built” designs
- ◆ (Re-)structuring for analysis is often necessary
 - ◆ Analyzable designs are more understandable and modifiable
 - ◆ **BUT ...** real designs are seldom structured as we want
 - ◆ **AND WORSE ...** there are good reasons for “bad” structure in source code
 - ▲ We must accept that the relation between a verified design and the “as built” structure of a system will not be simple
